#### Structure

Runtime Example Minsort

**Basic Operations** 

Runtime analysis

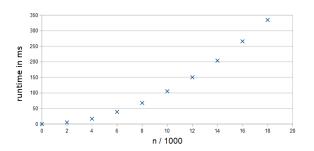

Minsort

Heapsort

Introduction to Induction

#### Logarithms

#### How long does the program run?

- In the last lecture we had a schematic
- **Observation:** it is going to be "disproportionately" slower the more numbers are being sorted
- How can we say more precisely what is happening?

#### How can we analyze the runtime?

- Ideally we have a formula which provides the runtime of the program for a specific input
- **Problem:** the runtime is depends on many variables, especially:
  - What kind of computer the code is executed on
  - What is running in the background
  - Which compiler is used to compile the code
- **Abstraction 1:** analyze the number of basic operations, rather than analyzing the runtime

#### Incomplete list of basic operations:

- $\blacksquare$  Arithmetic operation, for example: a + b
- Assignment of variables, for example: x = y
- Function call, for example: minsort(lst)

#### Better:

lines of machine code

#### Best:

process cycles

#### **Important:**

The actual runtime has to be roughly proportional to the number of operations.

How many operations does Minsort need?

- Abstraction 2: we calculate the upper (lower) bound, rather than exactly counting the number of operations
  Reason: runtime is approximated by number of basic operations, but we can still infer:
  - Upper bound
  - Lower bound

#### ■ Basic Assumption:

- $\blacksquare$  *n* is size of the input data (i.e. array)
- T(n) number of operations for input n

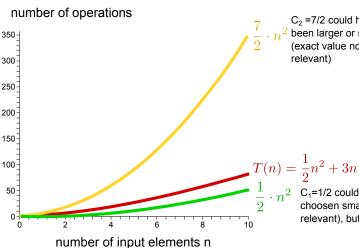

- **Observation:** the number of operations depends only on the size *n* of the array and not on the content!
- Claim: there are constants  $C_1$  and  $C_2$  such that:

$$C_1 \cdot n^2 \le T(n) \le C_2 \cdot n^2$$

This is called "quadratic runtime" (due to  $n^2$ )

## Runtime Example

C<sub>2</sub> =7/2 could have .  $n^2$  been larger or small (exact value not relevant)

> C<sub>1</sub>=1/2 could have been choosen smaller (not relevant), but not larger

## Runtime analysis - Minsort

#### We declare:

- $\blacksquare$  Runtime of operations: T(n)
- Number of Elements: n
- Constants:  $C_1$  (lower bound),  $C_2$  (upper bound)

$$C_1 \cdot n^2 \le T(n) \le C_2 \cdot n^2$$

■ Number of operations in round i:  $T_i$ 

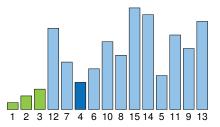

Figure: Minsort at iteration i = 4. We have to check n - 3 elements

## Runtime analysis - Minsort

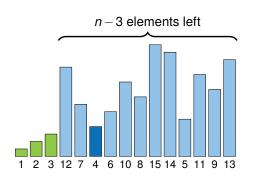

Figure: Minsort at iteration i = 4

## Runtime for each iteration:

$$T_1 \le C'_2 \cdot (n-0)$$
  
 $T_2 \le C'_2 \cdot (n-1)$   
 $T_3 \le C'_2 \cdot (n-2)$   
 $T_4 \le C'_2 \cdot (n-3)$   
 $\vdots$ 

$$T_{n-1} \leq C_2' \cdot 2$$

$$T_n \leq C_2' \cdot 1$$

$$T(n) = C'_2 \cdot (T_1 + \cdots + T_n) \leq \sum_{i=1}^n (C'_2 \cdot i)$$

#### Alternative: Analyse the Code:

```
def minsort(elements):
    for i in range(0, len(elements)-1):
         minimum = i
             if elements[j] < elements[minimum]:
    minimum = j

n-i-1
times
ninimum != i:</pre>
n-i-1
times
         for j in range(i+1, len(elements)):
            minimum != i:
             elements[i], elements[minimum] = \
                  elements[minimum]. elements[i]
```

return elements

$$T(n) \leq \sum_{i=0}^{n-2} \sum_{j=i+1}^{n-1} C_2' = \sum_{i=0}^{n-2} (n-i-1) \cdot C_2' = \sum_{i=1}^{n-1} (n-i) \cdot C_2' \leq \sum_{i=1}^{n} i \cdot C_2'$$

**Remark**:  $C_2'$  is cost of comparison  $\Rightarrow$  assumed constant

$$T(n) \leq \sum_{i=1}^{n} C'_{2} \cdot i$$

$$= C'_{2} \cdot \sum_{i=1}^{n} i$$

$$\downarrow \qquad \text{Small Gauss sum}$$

$$= C'_{2} \cdot \frac{n(n+1)}{2}$$

$$\leq C'_{2} \cdot \frac{n(n+n)}{2}, \ 1 \leq n$$

$$= C'_{2} \cdot \frac{2 \cdot n^{2}}{2} = C'_{2} \cdot n^{2}$$

Like for the upper bound there exists a  $C_1$ . Summation analysis is the same, only final approximation differs

$$T(n) \geq \sum_{i=1}^{n-1} C'_1 \cdot (n-i) = C'_1 \sum_{i=1}^{n-1} i$$

$$\geq C'_1 \cdot \frac{(n-1) \cdot n}{2} \quad \text{How do we get to } n^2?$$

$$\downarrow \qquad n-1 \geq \frac{n}{2} \text{ for } n \geq 2$$

$$\geq C'_1 \cdot \frac{n \cdot n}{2 \cdot 2} = \frac{C'_1}{4} \cdot n^2$$

## Runtime analysis - Minsort

#### **Runtime Analysis:**

■ Upper bound:  $T(n) \le C_2' \cdot n^2$ 

Lower bound:  $\frac{C_1'}{4} \cdot n^2 \le T(n)$ 

#### Summarized:

$$\frac{C_1'}{4} \cdot n^2 \le T(n) \le C_2' \cdot n^2$$

#### **Quadratic runtime proven:**

$$C_1 \cdot n^2 \le T(n) \le C_2 \cdot n^2$$

- The runtime is growing quadratically with the number of elements *n* in the list
- With constants  $C_1$  and  $C_2$  for which  $C_1 \cdot n^2 \le T(n) \le C_2 \cdot n^2$
- $3 \times$  elements  $\Rightarrow 9 \times$  runtime
  - $C = 1 \text{ ns} (1 \text{ simple instruction} \approx 1 \text{ ns})$
  - $n = 10^6$  (1 million numbers = 4 MB with 4 B/number)

$$C \cdot n^2 = 10^{-9} \text{ s} \cdot 10^{12} = 10^3 \text{ s} = 16.7 \text{ min}$$

- $\blacksquare$   $n = 10^9$  (1 billion numbers = 4GB)
  - $C \cdot n^2 = 10^{-9} \text{ s} \cdot 10^{18} = 10^9 \text{ s} = 31.7 \text{ years}$
- Quadratic runtime = "big" problems unsolvable

#### Intuitive to extract minimum:

- **Minsort:** to determine the minimum value we have to iterate through all the unsorted elements.
- Heapsort: the root node is always the smallest (minheap). We only need to repair a part of the full tree after the delete operation.

#### Formal:

- Let T(n) be the runtime for the Heapsort algorithm with n elements
- On the next pages we will proof  $T(n) \le C \cdot n \log_2 n$

#### Depth of a binary tree:

- **Depth** *d*: longest path through the tree
- Complete binary tree has  $n = 2^d 1$  nodes
- Example: d = 4⇒  $n = 2^4 - 1 = 15$

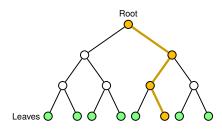

Figure: Binary tree with 15 nodes

#### **Basics:**

- You want to show that assumption A(n) is valid  $\forall n \in \mathbb{N}$
- We show induction in two steps:
  - Induction basis: we show that our assumption is valid for one value (for example: n = 1, A(1)).
  - Induction step: we show that the assumption is valid for all n (normally one step forward: n = n + 1, A(1), ..., A(n)).
- If both has been proven, then A(n) holds for all natural numbers n by **induction**

#### Claim:

A **complete** binary tree of depth d has  $v(d) = 2^d - 1$  nodes

■ **Induction basis:** assumption holds for d = 1

Root

$$v(1) = 2^1 - 1 = 1$$
  
 $\Rightarrow$  correct  $\checkmark$ 

Figure: Tree of depth 1 has 1 node

## Induction - Example 1

Number of nodes v(d) in a binary tree with depth d:

- Induction assumption:  $v(d) = 2^d 1$
- Induction basis:  $v(1) = 2^d 1 = 2^1 1 = 1$  ✓
- **Induction step:** to show for d := d + 1

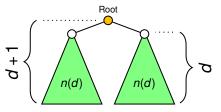

Figure: binary tree with subtrees

$$v(d+1) = 2 \cdot v(d) + 1$$

$$= 2 \cdot \left(2^{d} - 1\right) + 1$$

$$= 2^{d+1} - 2 + 1$$

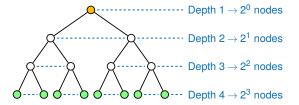

$$= 2^{d+1} - 1 \checkmark$$

 $\Rightarrow$  By induction:  $v(d) = 2^d - 1 \ \forall v \in \mathbb{N} \ \Box$ 

#### Heapsort has the following steps:

- Initially: heapify list of *n* elements
- **Then:** until all *n* elements are sorted
  - Remove root (=minimum element)
  - Move last leaf to root position
  - Repair heap by sifting

#### Runtime of heapify depends on depth d:

#### Runtime of heapify with depth of d:

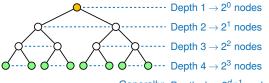

- No costs at depth d with  $2^{d-1}$  (or less) nodes
- The cost for sifting with depth 1 is at most 1*C* per node
- In general: sifting costs are linear with path length and number of nodes

# Runtime - Heapsort Heapify

## ZE.

#### Heapify total runtime:

Generally: Depth  $d \rightarrow 2^{d-1}$  nodes

Depth	Nodes	Path length	Costs per node	Upper bound
d	2 <sup>d-1</sup>	0	$\leq C \cdot 0$	≤ <i>C</i> · 1
<i>d</i> − 1	2 <sup>d-2</sup>	1	≤ <i>C</i> ⋅ 1	Standard $\leq C \cdot 2$
d-2	$2^{d-3}$	2	$\leq C \cdot 2$	Equation $\leq C \cdot 3$
<i>d</i> – 3	2 <sup>d-4</sup>	3	≤ <i>C</i> ⋅ 3	$\leq C \cdot 4$

$$T(d) \leq \sum_{i=1}^{d} \left( C \cdot (i-1) \cdot 2^{d-i} \right) \leq \sum_{i=1}^{d} \left( C \cdot i \cdot 2^{d-i} \right)$$

$$T(d) \le C \cdot \sum_{i=1}^{d} (i \cdot 2^{d-i}) \le C \cdot 2^{d+1}$$
  
See next slides

■ Hence: Resulting costs for heapify:

$$T(d) \leq C \cdot 2^{d+1}$$

■ **However:** We want costs in relation to *n* 

$$T(d) \leq C \cdot 2^{d+1}$$

- A binary tree of depth d has  $2^{d-1} \le n$  nodes
- $2^{d-1} 1$  nodes in full tree till layer d-1
- At least 1 node in layer d
- Equation multiplied by  $2^2$ ⇒  $2^{d-1} \cdot 2^2 < 2^2 \cdot n$
- Cost for heapify:  $\Rightarrow T(n) < C \cdot 4 \cdot n$

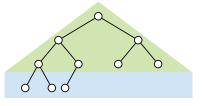

Figure: Partial binary tree

■ We want to proof (induction assumption):

$$\underbrace{\sum_{i=1}^{d} \left( i \cdot 2^{d-i} \right)}_{A(d) \leq B(d)} \leq 2^{d+1}$$

■ We denote the left side with A, the right side with B

$$A(d) \leq B(d)$$

$$\sum_{i=1}^{d} \left( i \cdot 2^{d-i} \right) \leq 2^{d+1}$$

$$\sum_{i=1}^{1} (i \cdot 2^{1-i}) \le 2^{1+1}$$

$$2^{0} \le 2^{2} \checkmark$$

#### Induction step: (d := d + 1):

■ **Idea:** Write down right-hand formula and try to get A(d) and B(d) out of it

$$A(d) \leq B(d) \qquad \Rightarrow \qquad A(d+1) \leq B(d+1)$$

$$\sum_{i=1}^{d+1} \left( i \cdot 2^{d+1-i} \right) \leq 2^{d+1+1}$$

$$2 \cdot \sum_{i=1}^{d+1} \left( i \cdot 2^{d-i} \right) \leq 2 \cdot 2^{d+1}$$

$$\vdots$$

## Induction - Example 2

#### Induction step: (d := d + 1):

:

$$2 \cdot \sum_{i=1}^{d+1} \left( i \cdot 2^{d-i} \right) \le 2 \cdot 2^{d+1}$$

$$2 \cdot \sum_{i=1}^{d+1} \left( i \cdot 2^{d-i} \right) \leq 2 \cdot B(d)$$

$$2 \cdot \sum_{i=1}^{d} \left( i \cdot 2^{d-i} \right) + 2 \cdot (d+1) \cdot 2^{d-(d+1)} \le 2 \cdot B(d)$$

$$2 \cdot A(d) + (d+1) \leq 2 \cdot B(d)$$

■ **Problem:** does not work but claim still holds

### Working proof:

Show a little bit stronger claim

$$\sum_{i=1}^{d} \left( i \cdot 2^{d-i} \right) \le 2^{d+1} - d - 2 \le 2^{d+1}$$

■ Advantage: results in a stronger induction assumption

$$\Rightarrow$$
 exercise

#### Runtime of the other operations:

- Constant costs for taking out  $n \times maximum$
- Maximum of d steps repairing the heap n times
- Depth of heap at the start is  $d \le 1 + \log_2 n$

$$2^{d-1} \le n \Rightarrow d-1 \le \log_2 n \Rightarrow d \le 1 + \log_2 n$$

- Recall: the depth and number of elements is decreasing
  - Hence:  $T(n) \le n \cdot (1 + \log_2 n) \cdot C$
  - We can reduce this to:

$$T(n) \le 2 \cdot n \log_2 n \cdot C$$
 (holds for  $n > 2$ )

#### **Runtime costs:**

- Heapify:  $T(n) \leq 4 \cdot n \cdot C$
- Remove:  $T(n) \le 2 \cdot n \log_2 n \cdot C$
- Total runtime:  $T(n) \le 6 \cdot n \log_2 n \cdot C$
- Constraints:
  - Upper bound:  $C_2 \cdot n \log_2 n \ge T(n)$  (for  $n \ge 2$ )
  - Lower bound:  $C_1 \cdot n \log_2 n \le T(n)$  (for  $n \ge 2$ )
  - lacksquare  $\Rightarrow$   $C_1$  and  $C_2$  are constant

## Logarithm to different bases:

$$\log_a n = \frac{\log_b n}{\log_b a} = \log_b n \cdot \frac{1}{\log_b a}$$

The only difference is a constant coefficient  $\frac{1}{\log_b a}$ 

#### **Examples:**

$$\log_2 4 = \log_{10} 4 \cdot \frac{1}{\log_2 10} = 0.602 \dots \cdot 3.322 \dots = 2 \checkmark$$

■ 
$$\log_{10} 1000 = \log_e 1000 \cdot \frac{1}{\log_e 10} = \ln 1000 \cdot \frac{1}{\ln 10} = 3$$
 ✓

### Runtime of $n \log_2 n$ :

■ Assume we have constants  $C_1$  and  $C_2$  with

$$C_1 \cdot n \cdot \log_2 n \le T(n) \le C_2 \cdot n \cdot \log_2 n$$
 for  $n \ge 2$ 

- $\blacksquare$  2× elements  $\Rightarrow$  only slightly larger than 2× runtime
  - $\blacksquare$  *C* = 1 ns (1 simple instruction  $\approx$  1 ns)
  - $n = 2^{20}$  (1 million numbers = 4 MB with 4 B/number)

$$C \cdot n \cdot log_2 n = 10^{-9} \text{ s} \cdot 2^{20} \cdot 20 = 21.0 \text{ ms}$$

- $n = 2^{30}$  (1 billion numbers = 4GB)
  - $C \cdot n \cdot log_2 n = 10^{-9} \text{ s} \cdot 2^{30} \cdot 30 = 32 \text{ s}$
- Runtime  $n \log_2 n$  is nearly as good as linear!
